A First-order Simplification Rule with Constraints

giese@ira.uka.de

Abstract. Several variants of a first-order simplification rule for non-normal form tableaux using syntactic constraints are presented. These can be used as a framework for porting refinements of clausal first-order proof procedures to non-normal form tableaux. Some experimental results obtained with a prototypical implementation are given.

1 Introduction

Non-normal form analytic tableaux have a number of advantages over the proof procedures for clausal form implemented in most successful automated theorem provers. For instance, when the logic is enhanced by modal operators, clausal form cannot be used without previously translating the problems into first-order. Another case is the integration of automated and interactive theorem proving [1,8], where normal forms would be counter-intuitive. Unfortunately, standard non-normal form tableaux tend to be rather inefficient, as many of the refinements available to clausal procedures are hard to adapt.

In [11], Massacci presents a simplification rule for propositional and modal tableau calculi. This rule is of the form

$$\begin{array}{cc} \psi & \\ \phi & \end{array} \quad \overset{simp}{\rightsquigarrow} \quad \begin{array}{c} \psi[\phi] \\ \phi \end{array}$$

where $\psi[\phi]$ is the formula that results form first replacing any occurrence of ϕ in ψ by *true*,[1] and then applying a set of boolean simplifications of the form

$$\neg \mathit{true} \to \mathit{false}, \quad \neg \mathit{false} \to \mathit{true}, \quad \mathit{true} \wedge \phi \to \phi, \quad \mathit{false} \wedge \phi \to \mathit{false}, \quad \text{etc.}$$

to eliminate all occurrences of truth constants. Massacci shows that proof procedures using this rule can subsume a number of other theorem proving techniques for propositional logic, e.g. the unit rule of DPLL [7], the β^c rules of KE [6], regularity and hyper-tableaux [2]. This is done mainly by specifying the strategy of when and where to apply the *simp* rule. Much of the power of these and other formalisms (e.g. Stålmarck's Proof Procedure [13]) comes from simplification-like rules.

While DPLL and hyper-tableaux are originally formulated for problems in clause normal form (CNF), the simplification rule is applicable to arbitrary predicate logic formulae, making it a good framework to generalize CNF techniques to the non-normal form case. Massacci gives variants of the simplification rule for various modal logics.

[1] If $\phi = \neg\phi'$, any occurrence of ϕ' may be replaced by *false*. I will omit this complementary case throughout the paper for terseness' sake.

In [10], he also gives a variant of the rule for first-order free-variable tableaux. Unfortunately, this rule does *not* in general subsume first-order versions of unit-resolution, hyper-tableaux etc., because it places strong restrictions on the instantiation of free variables.

This paper presents variants of the simplification rule, that overcome this limitation.

2 Lifting with Constraints

Consider a free-variable tableau branch with the formulae $p(X) \vee q(X)$ and $\neg p(a)$, where X is a free variable. If X is instantiated with a, the disjunction may be simplified to $q(a)$. One possibility for lifting the simplification rule consists in applying a substitution to the whole proof, that unifies certain subformulae, so that a simplification becomes possible.

Such a rule would be formulated using the most general unifier (mgu) of the simplifying formula and some subformula of the simplified formula. A little care must be taken to prevent the instantiation of bound variables by such a unifier. We call (an occurrence of) a subformula ξ of ϕ *simplifiable*, if no variable occurring free in ξ is bound by ϕ. So $p(x)$ is simplifiable in $\exists y.(q(y) \wedge p(x))$, but not in $\exists x.(p(y) \wedge p(x))$. It is also simplifiable in $(\exists x.q(x)) \wedge p(x)$, because the quantifier does not bind the x occurring free in $p(x)$.

Using this notion, a simplification rule with global instantiation can be given:[2]

$$\begin{array}{cc} \psi & \\ \phi & \end{array} \quad \overset{simp}{\rightsquigarrow} \quad \begin{array}{c} \mu(\psi)[\mu(\phi)] \\ \mu(\phi) \end{array}$$

where μ is a mgu of ϕ and some simplifiable subformula of ψ,
and μ is applied on all open branches.

The problem with this approach is that it introduces a new backtracking choicepoint, because the applied unifier may not lead to a proof.

2.1 Unification constraints

A universal technique for avoiding the global application of substitutions is to decorate formulae with unification constraints. A unification constraint C is a conjunction of syntactic equalities between terms or formulae, written as

$$s_1 \equiv t_1 \,\&\, \ldots \,\&\, s_k \equiv t_k \quad .$$

We use the symbol $\equiv$ for syntactic equality in the constraint language to avoid confusion with the meta-level $=$. Let

$$\mathrm{Sat}(C) = \{\sigma \mid \text{for all } i,\ \sigma(s_i) \text{ equals } \sigma(t_i) \text{ syntactically}\}$$

be the set of ground substitutions satisfying a constraint. A constraint is called satisfiable, if $\mathrm{Sat}(C)$ is not empty, which means that there is a simultaneous unifier for

[2] We use a non-standard notation for tableau rules: the formulae on the left are required to be on the branch and are *replaced* by the ones on the right. This notation has the advantage of making clear which formulae need to be retained after the rule application.

the pairs $\{s_i, t_i\}$. A constraint C subsumes a constraint D, iff $\mathrm{Sat}(D) \subseteq \mathrm{Sat}(C)$. Two constraints C and D are equivalent, iff $\mathrm{Sat}(C) = \mathrm{Sat}(D)$.

A formula ϕ with constraint C is written as $\phi \ll C$. The intuition is to consider the formula ϕ as present, only if the free variables are instantiated in a way that satisfies the constraint. The empty constraint, which is satisfied by all ground substitutions, is usually omitted. Instead of globally applying a mgu of two formulae ϕ and ψ to the proof, when a rule application requires some instantiation of free variables, we can annotate the formulae resulting from the rule application with a constraint $\phi \equiv \psi$, which is a local operation that does not lead to a backtracking choicepoint. For instance, simplification of $p(X) \vee q(X)$ with $\neg p(a)$ requires instantiation of X with a leading to $\mathit{false} \vee q(a) \ll X \equiv a$, which is rewritten to $q(a) \ll X \equiv a$.

Obviously, if formulae $\phi_i \ll C_i$ which already carry constraints are involved in a rule application, the conjunction $C_0 \,\&\, C_1 \ldots$ has to be passed on to the resulting formulae. This is referred to as constraint *propagation*.

Constraints are propagated through rule applications, until a branch is closed. Closure between two literals $L \ll C$ and $\neg L' \ll C'$ is only allowed if the constraint $C \,\&\, C' \,\&\, L \equiv L'$ is satisfiable.

Using unification constraints, the simplification rule takes the form

$$\begin{array}{ll} \psi \ll C & \\ \phi \ll D & \overset{simp^{c0}}{\rightsquigarrow} \end{array} \quad \begin{array}{l} \psi \ll C \\ \phi \ll D \\ \mu(\psi)[\mu(\phi)] \ll (C \,\&\, D \,\&\, \phi \equiv \xi) \end{array}$$

where ξ is a simplifiable subformula of ψ,
μ is a mgu of ξ and ϕ,
and $C \,\&\, D \,\&\, \phi \equiv \xi$ is satisfiable

Theorem 1. *The $simp^{c0}$ rule is sound in a free variable tableau calculus with constraints.*

Proof sketch. Let σ be (a ground specialization of) the instantiation used to close a proof. Consider the ground proof-tree obtained by applying σ to all formulae, and omitting those formulae with constraints not satisfied by σ. The resulting proof is easily seen to be closed, and uses a ground version of the simplification rule, which is obviously sound.

It is a little misleading to call $simp^{c0}$ a simplification rule, because the original formula $\psi \ll C$ has to be retained for completeness. There is however an important special case: if $D \,\&\, \phi \equiv \xi$ subsumes C, the original formula $\psi \ll C$ may be discarded. Let $simp^{c1}$ be the rule obtained with this modification.

Theorem 2. *The $simp^{c1}$ rule is sound. It is also complete, i.e. a tableaux branch that can be closed by a refutation R, can still be closed by a modified refutation R' after an application of the $simp^{c1}$ rule. Moreover, there is an R' that is at most as large as the original R.*[3]

Proof sketch. Soundness follows from Theorem 1. The rest is shown by constructing R' from R by a proof transformation, in which rule applications on (descendents of)

[3] Note, that the $simp^{c1}$ application is not counted in R'. So the overall proof size may increase by 1.

a discarded original formula $\psi \ll C$ can either be applied to (descendents of) the simplified formula, or be discarded altogether.

The $simp^c$ rules enjoy an interesting finiteness property. Call two constrained formulae $\phi \ll C$, $\psi \ll D$ *variants*, if C and D are equivalent and for all $\sigma \in \mathrm{Sat}(C)$, $\sigma(\phi) = \sigma(\psi)$. E.g. $p(X) \ll X \equiv a$ and $p(a) \ll X \equiv a$ are variants.

Theorem 3. *Starting from a given tableau branch, only a finite number of α, β, δ and $simp^{c0}$ rule applications without intervening applications of the γ rule are possible, if $simp^{c0}$ is never applied twice to the same pair of constrained formulae, and any formula which is a variant of a formula already present on a branch is discarded.*[4] *The same is true for the $simp^{c1}$ rule.*

Proof sketch. A formula ϕ can only be simplified by setting one of its subterms to *true* or *false*, and the resulting simplified formulae are all smaller than ϕ. So the number of distinct formulae that can be generated is finite. On the other hand, all constraints that could be generated are conjunctive combinations of existing constraints and syntactic equations between subformulae of formulae on a branch, so there can be only finitely many non-equivalent constraints. Accordingly, the number of non-variant constrained formulae must be finite. For $simp^{c1}$ even less rule applications are possible, so the same argument holds.

As a practical consequence of this finiteness property, there is no need to interleave γ and $simp^c$ applications in a proof procedure to guarantee fairness. It is possible to apply all possible simplifications before considering an application of the γ rule.

2.2 Dis-unification constraints

In most cases, the original formula $\psi \ll C$ has to be kept on the branch in the $simp^{c1}$ rule. This can lead to redundancies as exemplified by the following tableau branch for the set of formulae $\{p(a), q(a), \neg p(X) \vee \neg q(X) \vee r(X)\}$:

$$\begin{gathered} 1 : p(a) \\ 2 : q(a) \\ 3 : \neg p(X) \vee \neg q(X) \vee r(X) \\ 4 = simp(3,1) : \neg q(a) \vee r(a) \ll X \equiv a \\ 5 = simp(3,2) : \neg p(a) \vee r(a) \ll X \equiv a \end{gathered}$$

After generation of 4, formula 5 is redundant, because if X is actually instantiated with a as the constraint of 5 demands, formula 3 could have been discarded after generating 4. $q(a)$ only needs to be used to simplify 4, leading to $r(a) \ll X \equiv a$. In the presence of a large formula and many simplifying literals, a large number of such redundant formulae may be generated.

One way of overcoming this problem is to record instantiations under which a formula could have been discarded in the constraint. To do this, we have to require the constraint language to be closed under negation (denoted '!') as well as conjunction. The resulting constraint satisfiability problems are known as *dis-unification* problems, see e.g. [5], so I will talk of dis-unification or DU constraints.

[4] This might be enforced through a regularity condition that forbids the application of a rule that would lead to variant formulae on one of the extended branches.

A little care has to be taken with the semantics of DU constraints: Some DU constraints that are not satisfiable in the current signature might become satisfiable when the signature is extended. E.g., $!X \equiv a$, is not satisfiable in a signature consisting only of the constant symbol a, but it is satisfiable in any extended signature. In our context, satisfiability should be considered with respect to a possibly extended signature, because new skolem symbols might be introduced at a later point. In practice, it turns out that the satisfiability and subsumption checks actually get simpler with this definition. The same effect for term ordering constraints was noted in [12].

Using DU constraints, the simplification rule can be reformulated as follows:

$$\begin{array}{c} \psi \ll C \\ \phi \ll D \end{array} \overset{simp^{c2}}{\rightsquigarrow} \begin{array}{c} \psi \ll C \,\&\, !(D \,\&\, \phi \equiv \xi) \\ \phi \ll D \\ \mu(\psi)[\mu(\phi)] \ll (C \,\&\, D \,\&\, \phi \equiv \xi) \end{array}$$

where ξ is a simplifiable subformula of ψ,
μ is a mgu of ξ and ϕ,
and $C \,\&\, D \,\&\, \phi \equiv \xi$ is satisfiable

In addition, we allow formulae with unsatisfiable constraints to be discarded. One easily checks, that this makes it possible to discard ψ at least in all those cases, where $simp^{c1}$ allows it.

The example above now becomes

$$\begin{array}{c} 1 : p(a) \\ 2 : q(a) \\ 3 : \neg p(X) \vee \neg q(X) \vee r(X) \end{array} \rightsquigarrow \begin{array}{c} 1 : p(a) \\ 2 : q(a) \\ 3 : \neg p(X) \vee \neg q(X) \vee r(X) \ll !\, X \equiv a \\ 4 : \neg q(a) \vee r(a) \ll X \equiv a \end{array}$$

The constraint $!\, X \equiv a$ now prevents the simplification of 3 with 2. Simplification of 4 with 2 gives a new constraint of $X \equiv a \,\&\, !\, X \equiv a$ for 4, which is unsatisfiable, so 4 can be discarded after adding the literal $r(a) \ll X \equiv a$

Theorems 2 and 3 also hold for the $simp^{c2}$ rule. The principal drawback of this variant is the high complexity of dis-unification. As a compromise, it is possible to keep unification (U) and dis-unification (DU) parts of constraints separate and to weaken the DU part of constraints if convenient. The unification part has to be left alone, as it is relevant for soundness. The DU part only serves to reduce the necessary proof search, so it may be thrown away without losing correctness.

One possible approach consists in restricting oneself to constraints of the form $C_0 \,\&\, !\, C_1 \,\&\, !\, C_2 \ldots$, where the C_i are conjunctive unification constraints as in Sec. 2.1. Here, C_0 is the U part and $!\, C_1 \,\&\, !\, C_2 \ldots$ the DU part of the constraint. The DU part of the constraint of a formula is discarded before it is used to simplify another one, in order to maintain this form for all constraints. Satisfiability and subsumption (for possibly extended signatures) are fairly easy to check for these constraints.

3 Using Universal Variables

In practice, the simplification rules as outlined above tend to require a lot of instances of γ-formulae. E.g., given the formulae $\{p(a), p(b), p(c), \forall x. \neg p(x) \vee q(x)\}$, one can produce after one γ expansion the literals $q(a) \ll X \equiv a$, $q(b) \ll X \equiv b$, and

$q(c) \ll X \equiv c$. But these literals have mutually contradictory constraints, so any further rule application or closure can involve at most one of these literals. One needs three instances of the γ formula to produce the compatible literals $q(a) \ll X_1 \equiv a$, $q(b) \ll X_2 \equiv b$, and $q(c) \ll X_3 \equiv c$. But with three instances, not only these three useful literals are deducible, but a total of nine q-literals coming from the simplification of each instance $\neg p(X_i) \vee q(X_i)$ with each of the three p-literals. As all of these will subsequently be used to simplify any q-subformula on the branch, this can quickly lead to a huge (though finite) number of rule applications.

One way to reduce the number of distinct instances of γ formulae is to use universal variables, see e.g. [4].[5] A free variable x is called *universal* with respect to a formula ϕ on a tableau branch, if $\forall x.\phi$ is a logical consequence of the formulae on a branch. All other free variables are called *rigid*. This property is of course undecidable. In practice, one uses simple sufficient criteria to detect universality of free variables, the most common one being to flag all free variables introduced in a γ extension as universal, and to preserve universality through all non-splitting rule applications. After a β rule application, those free variables which occur on more than one of the subformulae become rigid. The benefit of universal variables is that they may be instantiated independently for all formulae and may also be renamed as needed, whereas rigid variables have to be instantiated identically on all branches.

I shall write $[\bar{X}]\phi \ll C$ for a constrained formula with universal variables $\bar{X}$. Using universal variables, the following derivation is possible:

$$\begin{array}{c} p(a) \\ p(b) \\ p(c) \\ \forall x.\neg p(x) \vee q(x) \\ [X]\neg p(X) \vee q(X) \end{array} \overset{3\times simp}{\rightsquigarrow} \begin{array}{c} p(a) \\ p(b) \\ p(c) \\ \forall x.\neg p(x) \vee q(x) \\ [X]\neg p(X) \vee q(X) \ll !\, X \equiv a \,\&\, !\, X \equiv b \,\&\, !\, X \equiv c \\ [X]q(a) \ll X \equiv a \\ [X]q(b) \ll X \equiv b \\ [X]q(c) \ll X \equiv c \end{array}$$

The resulting literals are no longer incompatible, because X may be instantiated differently for each of them. It is of course possible to eliminate the universal variable and constraint altogether in these literals, but that is a technical optimization which is not strictly necessary.

Formally, in a simplification, all free variables in the result that were universal in one of the original formulae may be flagged as universal in the result:

$$\begin{array}{c} [\bar{X}]\psi \ll C \\ [\bar{Y}]\phi \ll D \end{array} \overset{simp^{c2u}}{\rightsquigarrow} \begin{array}{c} [\bar{X}]\psi \ll C \,\&\, !(D \,\&\, \phi \equiv \xi) \\ [\bar{Y}]\phi \ll D \\ [\bar{X} \cup \bar{Y}]\mu(\psi)[\mu(\phi)] \ll (C \,\&\, D \,\&\, \phi \equiv \xi) \end{array}$$

where ξ is a simplifiable [6] subformula of ψ,
μ is a mgu of ξ and ϕ,
and $C \,\&\, D \,\&\, \phi \equiv \xi$ is satisfiable

[5] They have been used to solve a similar problem in equality handling in [3].

[6] The 'simplifiable subformula' condition could be relaxed to permit, e.g. the simplification of $\exists y.p(y)$ with $[X].p(X)$, but this becomes rather technical, so we won't do it in this paper.

This rule is sound and complete for the free-variable tableau calculus with universal variables, but there is a difficulty with the finiteness property. To get the full power out of this rule, it is necessary to rename universal variables in the original formulae to make them disjoint. But this renaming destroys finiteness. Consider for instance the formulae $p(a)$ and $[X]\neg p(X)\vee p(f(X))$. With simplification and renaming of universal variables, it is possible to consecutively deduce

$$[X_1].p(f(a)) \ll X_1 \equiv a$$
$$[X_1, X_2].p(f(f(a))) \ll X_1 \equiv a \,\&\, X_2 \equiv f(a)$$
$$[X_1, X_2, X_3].p(f(f(f(a)))) \ll X_1 \equiv a \,\&\, X_2 \equiv f(a) \,\&\, X_3 \equiv f(f(a))$$
$$\text{etc.}$$

This means, that in general simplification and γ instantiation need to be interleaved to retain fairness. As the $simp^{c2u}$ rule *without* renaming obviously enjoys the finiteness property, one might alternatively interleave renaming and γ instantiation, but that would amount to ignoring universality for most of the time.

There are problems, like e.g. Schubert's Steamroller [14], or the 'Natural Language' problems submitted to this FTP workshop,[7] in which simplification with universal variables actually always terminates. To handle these cases efficiently, it is advisable to equip a proof procedure with some sort of cycle detection, that only interleaves simplifier applications with γ rules, if they threaten to lead to infinite simplification sequences. One possibility is to set a limit to the size of inferred formulae, which can be incrementally increased as γ rules are applied. This would always allow rule applications which really simplify a formula in the sense of making it smaller.[8]

4 Experimental Results

PrInS is a theorem prover implemented in the Java programming language. It uses a simplification rule with universal variables, but only uses unification constraints. Like leanT^AP, it works on formulae in negation normal form (NNF) for simplicity, but it would be easy to extend it to non-normal form tableaux. To avoid redundancy, it uses a NNF variant of positive hyper-tableaux:

- Only positive literals are used for simplification.
- Only negative literal subformulae of β-formulae are simplified, and only those negative literals which are leftmost on a disjunctive path.
- For the sake of simplicity, simplification is not performed below quantifiers.
- β expansion is only performed on formulae with at least one disjunctive path that contains only positive literals or quantified formulae.
- β applications not needed for a closure are *pruned*, see e.g. [4,2].

Instantiation of rigid variables is handled by a backtracking-free process outlined in [9]. No equality handling is built in, so the standard axiomatization is used, which leads to poor performance on equality problems.

[7] See `http://www.uni-koblenz.de/ftp00/ProblemSets/`

[8] Another possibility might be to force interleaving on simplifications in which a formula is used to simplify one of its own ancestors, but the author is not sure whether this condition guarantees finiteness in all cases.

Running on a 440 MHz Sun SPARC Ultra 10 with JDK 1.2, PrInS can prove, resp. disprove all of the 'johan' problems in the FTP'00 'Natural Language' set in a total of 4.0 CPU seconds. Of the 97 problems in the 'Mathematics' set, 68 are proven and 2 disproven with a time limit of 15 seconds per problem.

Schubert's Steamroller in the TPTP PUZ031+1 formulation is solved in 0.6 seconds. Of the 73 Pelletier problems in the TPTP collection (FOF formulations were taken where available), 63 are solved in 2.3 seconds. The size 8 pigeonhole problem, MSC007-1.008, is solved in 85 seconds. The ones not solved are mainly from the GRP and LCL categories.

To our knowledge, comparable results have not previously been achieved with a non-clausal tableaux prover.

5 Conclusion

Several possibilities for a first-order version of the simplification rule of Massacci [10,11] were presented. Instead of globally applying unifying substitutions, syntactic constraints are used. Besides soundness and completeness, a finiteness property is discussed, which is important for the design of fair proof procedures. Experimental results are quoted, which show that an efficient proof procedure can be implemented using non-clausal tableaux with a simplification rule.

Further work includes the refinement of cyclicity tests and development of more goal-oriented simplification strategies than the currently implemented hyper-tableaux variant.
